

# Statistics 203: Introduction to Regression and Analysis of Variance

## *Functional Data*

Jonathan Taylor

# Today's class

## ● Today's class

- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Functional data.
- A functional  $t$ -test.
- Mean, variance, covariance functions.
- Functional data I care about – fMRI.

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

# Functional data

# Functional data

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convoluted design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Last class, we talked about smoothing one function at a time.
  - ◆ B splines;
  - ◆ smoothing splines;
  - ◆ kernel smoothers.
- In a functional data setting we observe *many* functions at once, we might also observe many covariates for each curve.
- Example I will talk about later: functions are space-time images, covariates are simple: “motion correction” and “slow drift.”

# A two-sample functional $t$ -test

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Suppose we observe a group of  $n$  paired curves: maybe the growth curves of twins separated at birth over the first 18 years of life but raised in different countries with a big difference in standard of living.
- Nutrition is known to have an effect on population height: twins' curves might be different.
- We can describe this data as  $(Y_{i1,t}, Y_{i2,t}), 1 \leq i \leq n, 0 \leq t \leq 18$  where twins  $Y_{.1}$  are in country # 1 and  $Y_{.2}$  are in country # 2 with

$$Y_{ij,t} = \mu_{i,t} + \delta_t \cdot 1_{\{j=1\}} + \varepsilon_{ij,t}.$$

- The measurement noise  $\varepsilon$  can be assumed independent across subjects and set of twins put probably is dependent in time ( $\mu_i$  would be a random effect curve for the  $i$ -th set of twins), and  $\delta$  is the “nutrition effect”
- Although we never observe the *whole* curve, we should think of actually having an entire curve.

# Functional $t$ -test

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convoluted design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- For each  $t$ , and each pair compute

$$\hat{\delta}_t = \frac{1}{n} \sum_{i=1}^n Y_{i1,t} - Y_{i2,t},$$

- Also, compute

$$\hat{\sigma}^2(\hat{\delta}_t) = \frac{1}{n-1} \sum_{i=1}^n (Y_{i1,t} - Y_{i2,t} - \hat{\delta}_t)^2$$

- Natural to use

$$T_t = \frac{\hat{\delta}_t}{\hat{\sigma}(\hat{\delta}_t)}$$

to test  $H_{0,t} : \delta_t = 0$ , i.e. at age  $t$  the “country effect” is 0.

- Test for no effect  $H_0 = \cap_t H_{0,t}$ : use

$$T_{\max} = \max_{t \in [0,18]} |T_t|.$$

# Smooth noise

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Problem: what is the distribution of  $T_{\max}$ ? It is not  $\chi^2$ ! Depends on properties of  $\varepsilon$ .
- Maybe we model each noise  $\varepsilon_{ij}$  as a smooth Gaussian process on  $[0, 18]$ .
- What is a Gaussian process? A random function such that for every collection  $\{t_1, \dots, t_k\}$  the random vector

$$(\varepsilon_{t_1}, \dots, \varepsilon_{t_k})$$

is multivariate normal.

- A Gaussian process  $\varepsilon_t$  is completely determined by

$$\mu_t = \mathbb{E}(\varepsilon_t), \quad R_{t,s} = \text{Cov}(\varepsilon_t, \varepsilon_s)$$

- If  $n$  is large (so  $T_t$  is almost Gaussian itself) then the distribution of

$$\varepsilon_{\max} = \max_{t \in [0, 18]} \varepsilon_t$$

depends on  $\text{Var}(\dot{\varepsilon}_t)$  (known as Rice's formula).

# Another approach

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Perhaps a more typical FDA approach would be “dimension” reduction. That is, take each curve  $Y_{ij,t}$  and express it as a linear combination of basis functions  $b_k(t)$  – the projection of  $Y_{ij,t}$  onto the basis

$$Y_{ij,t} = \sum_k c_{ij,k} b_k(t) + r_{ij,t}$$

Sometimes the remainder  $r_{ij,t} = 0$  and no dimension reduction is used.

- In any case, once you have expressed each curve in a given basis, the two-sample  $t$ -test problem becomes a standard regression problem involving the coefficients  $c_{j,k}$  which is the “new data.”
- With this basis approach, it is possible to impose penalties (i.e. on the second derivatives, etc.) as long as you know how to compute the penalties in your specific basis.

# Penalty example: second derivative

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convoluted design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Suppose we choose to express each curve  $Y_{ij,t}$  as a linear combination of  $\cos$  waves of the form

$$b_k(t) = \cos(2\pi kt/18), 1 \leq k \leq m.$$

- Then

$$b_k''(t) = c_k b_k(t), \quad \int_0^{18} b_k(t) b_j(t) dt = \delta_{jk} c_k'.$$

- This means that

$$\int_0^T \left( \sum_k a_k b_k''(t) \right)^2 dt = \sum_k a_k^2 c_k^2 c_k'.$$

- Smoothing spline problem to estimate  $\delta$  (penalty on integral of  $\delta''(t)^2$ ) becomes a ridge problem.

# Smoothing spline and ridge

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- Suppose we look at the two-sample problem in the Fourier basis but we impose a second derivative penalty. Let

$$\hat{Y}_{ij,t} = \sum_{k=1}^m c_{ij,k} b_k(t)$$

be the “dimension reduced”  $Y_{ij,t}$ ’s and

$$\delta_t = \sum_k \delta_k b_k(t)$$

be a linear combination of sine waves.

- Problem find  $\hat{\delta}_t$  that minimizes

$$L_\lambda(\delta) = \sum_{i=1}^n \left( \hat{Y}_{i1,t} - \hat{Y}_{i2,t} - \delta_t \right)^2 dt + \lambda \int_0^{18} \delta''(t)^2 dt.$$

- Both integrals reduce to sums involving  $\delta_k$ ’s and  $c_{ij,k}$ ’s: equivalent to a ridge problem.

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

# fMRI

# What is fMRI?

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- fMRI (Functional Magnetic Resonance Imaging) is a space-time recording of “metabolic activity” in the human brain
- “paradigm” (motor task, i.e. finger tapping or cognitive task, i.e. face recognition) increases nerve cell activity in areas associated with the “paradigm”
- increased nerve cell activity increases metabolic demand for oxygen, increases metabolic activity results in a lagged increase in oxygenated Hg (hemoglobin)
- relationship between input “paradigm” and BOLD is modelled through a transfer function, the Hemodynamic Response Function (HRF)

$$\text{BOLD}_{x,t} = \beta_x^{\text{Input}} \cdot (\text{HRF} * \text{Input})_t + \sum_{i=1}^k \beta_{i,x} X_i + \text{Err}_{x,t}.$$

# Block design – finger tapping

# Hemodynamic response function

# Convolved design – finger tapping

# Components of $\text{Err}_{x,t}$

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- physiological noise
  - ◆ cardiac noise
  - ◆ respiratory noise
  - ◆ basal metabolism
- motion artifacts
- saturation of signal
- other sources of error: lumped into “noise term”  $\varepsilon_{x,t}$

# Full model for finger tapping data

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

$$\text{BOLD}_{x,t} = \beta_x^{\text{Input}} \cdot (\text{HRF} * \text{Input})_t + \sum_{j=1}^6 T_{j,t} \beta_{j,x}^{\text{Motion}} + \sum_{j=0}^2 \beta_{j,x}^{\text{Time}} t^j + \varepsilon_{x,t}.$$

- Usually, model is fit voxel-by-voxel, usually spatial ignoring correlation between  $\varepsilon_{x_1,\cdot}$  and  $\varepsilon_{x_2,\cdot}$ .
- Most common model is a two-stage procedure: first find a (smoothed) AR(1) coefficient image at each voxel in the brain: estimate standard errors and coefficients with this AR(1) value at each voxel.  
Sometimes, even correlation within time series at a single point is ignored and model is fit by OLS.
- Many people work on “improving” this basic model.

# Voxel in the motor cortex

# Marginally significant voxel

# Real experiment: reward anticipation

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- B. Knutson, my psychologist collaborator is interested in reward anticipation.
- Subjects play simple video game, and are told whether they can win, lose or draw on each round.
- If we contrast “win” (reward) vs. “draw” (neutral), we will find areas that are sensitive to anticipating reward.

# Combining subjects: fixed effect analysis

- Today's class
- What is fMRI?
- Block design – finger tapping
- Hemodynamic response function
- Convolved design – finger tapping
- Components of  $\text{Err}_{x,t}$
- Full model for finger tapping data
- Voxel in the motor cortex
- Marginally significant voxel
- Real experiment: reward anticipation
- Combining subjects: fixed effect analysis

- For each subject  $i$ , compute

$$T_x^{RwAnt,i} = \frac{\hat{\beta}_x^{RwAnt,i}}{SE(\hat{\beta}_x^{RwAnt,i})}.$$

- Transform subject-specific comparisons to Talairach space (common coordinates).
- Form group map

$$T_x = \frac{1}{\sqrt{n}} \sum_{i=1}^n T_x^{RwAnt,i}.$$

- Analogous to the role of  $T_t$  in “growth curve” example.
- Where to set the threshold? The uncorrected 0.05 threshold is 1.96. The generalizations of Rice's formula set the threshold around 4.5 or so. Let's look at the difference.
